**Faculty : Science and Technology**

Decision Support System (DSS) can gather various sources of information, choose relevant and related knowledge intelligently, and structure the decision process efficiently. The problem is how to develop DSS for forensic science (FS)? How to perform computerised forensic DNA analysis (FDA) in FS? Is it possible to reverse engineer the existing system and then reengineered them with enhancements? In this study, methods to be used are discovered after reverse engineering of the user interfaces from the existing system. Research activities are divided into three phases; design of architecture; develop prototype of Web-based DSS based on the proposed architecture; and evaluate the prototype. The outcomes of this research are the type of analysis determined, system architecture designed and prototype developed. A DSS for FDA is implemented using Bayesian networks (BN) and likelihood ratios (LR) methods. Through reverse engineering processes of existing system, Forensic DNA Databank of Malaysia (FDDM), Architecture of Decision Support for Forensic DNA (ADeFor) are designed for a reengineered system called Forensic DNA Analysis Software (ForAS). Data validation using five real case studies proved that results obtained using ForAS is almost 100% accurate. Usability study with domain

experts shows that in scale from 0 to 9, with score 7.33 for data representation, 7.22 for system's learnability, and 6.73 for overall reaction of the system, the designed architecture and the developed prototype is proven reliable and helpful for FDA in FS.

Sistem sokongan keputusan (DSS) dapat mengumpulkan pelbagai sumber maklumat, memilih ilmu yang berkaitan dan relevan secara pintar, dan menstrukturkan proses pembuatan keputusan dengan efisien. Masalahnya adalah bagaimanakah cara untuk membangunkan DSS untuk sains forensik (FS)? Bagaimanakah cara untuk melakukan analisis forensik DNA (FDA) menggunakan komputer? Bolehkah kejuruteraan terbalik daripada sistem yang sedia ada dibina semula dengan lebih banyak manfaat? Dalam kajian ini, kaedah yang patut digunakan hanya dapat dikenalpasti selepas kejuruteraan terbalik daripada antaramuka sistem yang sedia ada telah dilakukan. Aktiviti penyelidikan dapat dibahagikan kepada tiga fasa; rekabentuk senibina yang telah direkayasa semula, pembangunan prototaip DSS berasaskan Web yang dibina berdasarkan senibina; dan penilaian prototaip. Hasil penyelidikan ini termasuklah penemuan cara untuk melaksanakan analisis, senibina sistem yang direkabentuk dan prototaip yang dibangunkan. DSS untuk FDA diimplementasi menggunakan kaedah rangkaian Bayesian (BN) dan nisbah kebolehjadian (LR). Melalui proses kejuruteraan terbalik daripada sistem yang sedia ada, "Forensic DNA Databank of Malaysia" (FDDM), "Architecture of Decision

Support for Forensic DNA” (ADeFor) direkabentuk untuk sistem yang direkayasa semula yang dipanggil “Forensic DNA Analysis Software” (ForAS). Pengesahan data menggunakan lima kes sebenar membuktikan bahawa hasil yang diperolehi menggunakan ForAS adalah hampir 100% tepat. Kajian kepenggunaan dengan pakar forensik menunjukkan bahawa daripada skala 0 hingga 9, dengan skor 7.33 untuk persembahan data, 7.22 untuk tahap kemudahan bagi mempelajari sistem, dan 6.73 untuk reaksi keseluruhan terhadap sistem, senibina yang direkabentuk dan prototaip yang dibangunkan terbukti boleh dipercayai dan berguna untuk FDA di dalam FS.
