ACKNOWLEDGEMENT

First of all, I would like to thank Dr. Misbahul Amin, supervisor of my final year project, which always concern and spend most of the time to discuss, guide and giving advise to me.

Besides that, I also would like to thank Kak Asbah, Mr. Tarmizi and Mr. Ruzeman who help me a lot in giving suggestion and advise in the progressing of borrowing and booking chemicals and instruments.

Finally, I would like to thank all my fellow friends which given me advise and help me a lot while I am doing my final year project.

ABSTRAK

Dengan kehadiran sejenis bahan elektrolitik bertaburan atas permukaan suatu logam atau aloi akan mencetuskan suatu keadaan dikenali pengaratan. Alkali atau alkali logam adalah lebih cenderung untuk tindak balas ini. Logam Aluminium kebanyakannya digunakan untuk pembinaan dan lain kerana ia adalah ringan dan tahan kepada pengaratan.

Ciri-ciri pengoksidaan pada suhu rendah bagi Aluminium telah dikaji dengan kehadiran air laut, $MgCl_2$, $BaCl_2$, dan $BaCl_2$ pada suhu antara 80 hingga $200^{\circ}C$ dalam udara biasa. Morfologi bagi sampel dikaji dalam pemeriksaan macroskopik. Ini akan menunjukkan sampel karat dalam nisbah yang berlainan dengan kehadiran garam alkali logam.

ABSTRACT

The presence of an electrolytic deposit on a metal or alloy surface may bring about an accelerated environmental attack known as corrosion. Alkali or alkaline earth metal salts are capable to propagate this attack. Aluminium metal is used extensively in building and others due to its light weight and corrosion resistant materials.

The low temperature oxidation behavior of Aluminium has been investigated in presence of seawater, $MgCl_2$, $BaCl_2$ and $CaCl_2$ at temperature 80 to 200 $^{\circ}C$ in the open air. The morphologies of samples were examined on the basis of macroscopic examination. It has been shown that samples corrode at a different rate in presence of alkaline earth metal salts.
