ACKNOWLEDGEMENTS

I would like to deliver my sincere gratitude and deepest appreciation to my supervisor Professor Dr. Law Ah Theem for all the guidance and patience throughout the whole course of this project. With his supervision and advices, I manage to overcome the problems that sound impossible to me at the beginning.

I would like to extend my appreciation to Mr Chin Kam Yew and Professor Law's postgraduate students who had gave me valuable opinions and demonstration as needed.

My sincere thanks also goes to to all my helpers Mr Wong Mun Kein, Mr Ong Meng Chuan, Ms Liew Huey Jiun, Ms Teng Kim Ting, Ms Choo Kim Ming, Ms Lau Pei Kim, Mr Khoo Khai Sin, Ms Yong Pooi Ling, Ms Lee Sau Yee, Mr Cheah Eng Onn, Mr Khor Wee Liang, Mr. Yew Wooi Meng and Ms Low San San. Without their helping hands, all my sampling would not be done.

Last but no least, I also grateful to my beloved family for being understand for all this time. Thanks to my dear housemates and coursemates for all the amusement and cheerful moment that you all had brought to me.

ABSTRACT

The Terengganu state is partially bordered by 244 Km of coastline facing the South China Sea which there are dense oil exploration and maritime transportation activities. These activities are potential in causing oil pollution in the South China Sea. Tar balls are formed from oil spill residual on sea. It can be suspended in the sea or settled at the bottom for many years. It also can travel for a long journey before it is being washed up to the beach. In this period, it can undergo a series of weathering process to reduce low molecular weight hydrocarbons content.

This project aims to document the current qualitative and quantitative of tar balls distribution on the beach at Batu Rakit, KUSTEM and Teluk Ketapang. The sampling trips were conducted during Southwest and Northeast monsoon season in March of 2002, June of 2002, September of 2002, December of 2002 and January of 2003. The statistical tests (t-test) show that there are differences for tar balls distribution between the monsoon seasons. The Northeast monsoon season deposited more tar balls than the Southwest monsoon.

The tar balls intensity is consider high in the study area. The mean and ranges of tar ball intensity at Batu Rakit beach were 2.315 g.m^{-2} to 19.272 g.m^{-2} , at KUSTEM beach were 0.042 g.m^{-2} to 29.123 g.m^{-2} and at Teluk Ketapang beach were 0.0497 g.m^{-2} to 20.790 g.m^{-2} respectively. The results show the tar balls contain of carcinogenic compounds, which are harmful to human. Besides it is also undergo a series of weathering process such as photooxidation, biodegradation, dissolution and evaporation. The study shows that the Terengganu beaches are polluted by the Tar Balls.

ABSTRAK

Sebahagian negeri Terengganu disempadani dengan garisan pantai yang sepanjang 244 Km dan menghadap ke arah Laut China Selatan yang giat dengan aktiviti carigali minyak dan pengangkutan. Kesemua aktiviti ini berpotensi menyebabkan pencemaran minyak di Laut China Selatan. Bebola tar terbentuk daripada baki minyak tumpahan. Ia boleh terapung atau termendar di dasar laut untuk beberapa tahun dan mampu bergerak jarak yang jauh sebelum dihanyutkan ke atas pantai dengan dorongan arus laut. Dalam tempoh masa ini, ia akan mengalami satu proses iklim yang mampu mengurangkan kandungan hidrokarbon yang mempunyai berat molekulnya ringan.

Tujuan menjalankan kajian kualitatif dan kuantitatif dan mendokumendasikan data terkini mengenai taburan bebola tar di Batu Rakit, KUSTEM and Teluk Ketapang. Lawatan penyampelan telah dijalankan semasa Monsun Timur Laut dan Barat Daya pada bulan Mac 2002, Jun 2002, September 2002, Disember 2002 dan Januari 2003. Ujian statistik telah membuktikan terdapat perubahan ke atas taburan bebola tar di antara dua monsun yang terlibat. Monsun Timur Laut menghanyutkan lebih banyak bebola tar ke pantai berbanding Monsun Barat Daya.

Kepadatan bebola tar adalah tinggi di tempat kajian. Julat kepadatan purata bebola tar di stesen kajian masing-masing ialah 2.315 g.m^{-2} hingga 19.272 g.m^{-2} di pantai Batu Rakit, 0.042 g.m^{-2} hingga 29.123 g.m^{-2} di pantai KUSTEM dan 0.0497 g.m^{-2} hingga 20.790 g.m^{-2} di pantai Teluk Ketapang. Keputusan juga menunjukkan ia mempunyai elemen karsinogenik yang merbahayakan kesihatan manusia.. Ia juga mengalami proses iklim yang melibatkan fotokimia, penguraian biologi, pemelarutan dan pemeruapan. Berdasarkan analisa keputusan, ia menunjukkan pantai Terengganu adalah tercemar.
