## **ACKNOWLEDGEMENTS**

First, I would like to thank my supervisor, Prof. Dr. Faizah Shaharom, for her guidance, comments, encouragement and invaluable advice throughout this final year project.

Special thanks are extended to Puan Kartini, Encik Che Mohd Zan, Encik Shahrul and Encik Johari for their support and their able and willing assistance throughout the study. Their advice and understanding are deeply appreciated.

My thanks also go to my friends, who have always been there for me through thick or thin, thank you for your friendship and support. Shazrina, Asni, Aznizah, Murni and Md Razis for their never ending help and support.

Last but not least, I would like to thank my family especially my parents, for their undying love, emotional support, money support and understanding. Finally, my appreciation is dedicated to those who are involved directly or indirectly in helping me to complete this project.

## **ABSTRACT**

From October 2005 to January 2006, fifty striped catfishes *Pangasius hypophthalmus* were collected from a cage culture farm at Sungai Terengganu, Manir, Terengganu. The fish was used to examine the monogenetic trematode. This study revealed that *Pangasius hypophthalmus* from Sungai Terengganu were infected with species of monogenean that inhabit at the gills of the fish called *Thaparocleidus siamensis*. The total prevalence for the infection of the monogenean is 100% and the mean intensity is 98.4. From the prevalence and the mean intensity of the monogenean relate with water parameter we know that differences environmental conditions reflected in parasite prevalence and the mean intensity.

## **ABSTRAK**

Dari Oktober 2005 hingga Januari 2006, lima puluh ekor ikan patin *Pangasius hypophthalmus* telah dikumpul dari satu penternakan sangkar di Sungai Terengganu, Manir, Terengganu. Ikan ini digunakan untuk menguji kehadiran trematod monogenea. Daripada kajian didapati bahawa *Pangasius hypophthalmus* dari Sungai Terengganu telah dijangkiti monogenea yang dijumpai di insang ikan itu yang dipanggil *Thaparocleidus siamensis*. Jumlah kelaziman untuk jangkitan monogenea ialah 100% dan min keamatian jangkitan ialah 98.4. Dari jumlah kelaziman dan min keamatian jangkitan monogenea berkait dengan parameter air kita dapat ketahui bahawa perbezaan keadaan persekitaran memberi kesan kepada kelaziman dan min keamatian jangkitan.
