## ACKNOWLEDGEMENT

Bismillahirrahmanirrahim, in the name of Allah the Most Gracious and Merciful, alhamdulillah, the work of almost 10 month had finally came to an end. In this opportunity I would like to thank dozens of people that have contributed and helped me in so many ways in finishing my project.

A bucket of love and high appreciation I gave to my supervisor, Pn. Wahizatul Afzan Azmi, together with my co-supervisor, En. Amirrudin Ahmad for their helps and attention on my research. More, to En. Amir, thanks for the books. Not only that, to En. Syed Ahmad Rizal Tuan Nek, Tuan Haji Muhammad Razali Salam and Along, thank you for helping me at the whole time I was in the lab and while I was collecting my samples. I am grateful for having so many people helping me out each time I need somebody.

To my parent, Che Mat Taib and Zanariah Yusof together with my siblings and the whole family, thank you for being with me, supporting my study here. Sometimes I was too busy and no time to be home. Thank you for the understanding as well as the mental support you gave me.

A special thanks to Intan, Fidayu, Ashriah, Jatul, Fyeera, Matun, Naim, Shiela, Seh Ling and Syafiq too. This is for their helps, constructive critics and ideas in conducting this research. Without their patient and opinion, I would not be able to complete this research on time.

Thank you and May God bless us all.

## ABSTRACT

The study was conducted at eight streams in various parts of Terengganu and an estuary in Tumpat, Kelantan between 22 May 2006 until 13 October 2006. They were Sungai Jeneris, Sungai Nerus, Lata Tembakah, Lata Belatan, Sungai Kemat, Belukar Bukit and two unnamed streams of Bukit Bauk. A total of 1431 aquatic insects' individuals were collected, consisting of seven orders and 43 families. Perlidae from the order Plecoptera had the highest collected individuals (34%) followed with Hydropsychidae (22%) (order Trichoptera) and Heptageniidae (16%) (order Ephemeroptera). Lata Tembakah recorded the most individuals collected with 423 while Tumpat was the least with 46 individuals only. Rocky streams beds, fast flowing water with little debris and forest litter maximized the collection of aquatic insects in some streams. Family Biotic Index (FBI), Biological Monitoring Work Party (BMWP) and Average Score Per Taxon (ASPT), indicated that all study sites were in good water quality although some study sites were punctuated by agriculture and residential areas. Kruskal-Wallis analysis showed that all study sites had significant differences based on sites and the total numbers of individuals with significant value of 0.021 as well as between sites and the total numbers of species with significant value of 0.009. Dissolved oxygen (DO), and total suspended solid (TSS) interacted positively ( $r^2=0.833$ ,  $r^2=0.900$ ) with the number of individuals collected while water temperature was negatively ( $r^2=-0.731$ ) correlated. The study sites were also clustered according to their value of Sorensen's Coefficient of similarity. Based on this, Tumpat showed least similarity to all study sites, thus indicated that the sites probably very less similar to the others based on the occurrence of aquatic insects. Its brackish water might have an impact on the abundance of aquatic insects recorded there. Other sites which mainly are head water streams, relatively very similar in terms of aquatic insects' occurrences. From this study, it showed that aquatic insects reacted on component of habitat and their adaptation for the distribution and abundance.

**KAJIAN KE ATAS TABURAN DAN KEDAPATAN AKUATIK BERDASARKAN  
KAEDAH PENILAIAN PANTAS DI SUNGAI-SUNGAI DI TERENGGANU  
DAN MUARA TUMPAT, KELANTAN**

**ABSTRAK**

Kajian telah dijalankan ke atas lapan sungai di Terengganu dan satu kawasan muara di Tumpat, Kelantan. Sungai-sungai tersebut ialah Sungai Jeneris, Sungai Nerus, Lata Tembakah, Lata Belatan, Sungai Kemat, Belukar Bukit dan dua sungai di Bukit Bauk. Sejumlah 1431 individu serangga akuatik dapat di kutip yang terdiri daripada tujuh order dan 43 famili. Perlidae dari order Plecoptera menunjukkan jumlah individu terbanyak (34 %) selain Hydropsychidae (22 %) dari order Trichoptera dan Heptageniidae (16 %) dari order Plecoptera. Lata Tembakah mengumpulkan paling banyak individu dengan bilangan 423 dan Tumpat adalah yang paling sedikit iaitu 46 individu. Tumpat juga menunjukkan komposisi serangga akuatik yang agak berlainan. Permukaan sungai yang berbatu, aliran air yang deras, bersama-sama dengan sedikit sisa dan sampah hutan memaksimumkan kutipan serangga akuatik di sesetengah kawasan kajian. Menggunakan indeks-indeks biologi seperti Family Biotic Index (FBI), Biological Monitoring Work Party (BMWP) and Average Score Per Taxon (ASPT), dapat dilihat semua kawasan kajian mempunyai kualiti air yang baik walaupun di sesetengah kawasan, terdapat kegiatan pertanian dan penempatan. Analisis Kruskal-Wallis menunjukkan terdapatnya perbezaan antara kawasan kajian dengan jumlah individu dengan nilai signifikansi iaitu 0.021 dan kawasan kajian dengan jumlah spesis yang di sampel (0.009). Oksigen terlarut dan jumlah pepejal terampai menunjukkan perkaitan secara positif dengan jumlah individu yang di kumpul manakala suhu air berkait secara negatif. Kawasan kajian juga turut di kelaskan berdasarkan nilai persamaan Sorrenson Coefficient. Dari sini, jelas menunjukkan yang bahawa Tumpat berbeza dari kawasan kajian lain dan perbezaan ini berdasarkan kedapatan serangga akuatik. Air paya ini mungkin mempunyai impak ke atas kelimpahan serangga akuatik yang di rekodkan di sini. Kawasan lain yang semuanya air tawar secara relatifnya mempunyai kesamaan dalam kedapatan serangga akuatik. Hasil kajian mendapati serangga akuatik bergantung kepada komponen habitat dan adaptasi mereka dalam menentukan taburan dan kedapatannya di sesuatu kawasan kajian.
